

# C++ Structures

...Starting to think about objects

# Structure

- A Structure is a container, it can hold a bunch of *things*.
  - These things can be of any type.
- Structures are used to organize related data (variables) into a nice neat package.

# Example - Student Record

- Student Record:
  - Name            a string
  - HW Grades      an array of 3 doubles
  - Test Grades     an array of 2 doubles
  - Final Average   a double

# Structure Members

- Each *thing* in a structure is called *member*.
- Each *member* has a name, a type and a value.
- Names follow the rules for variable names.
- Types can be any defined type.

# Example Structure Definition

```
struct StudentRecord {  
    char *name;    // student name  
    double hw[3];  // homework grades  
    double test[2]; // test grades  
    double ave;    // final average  
};
```

# Using a struct

- By defining a structure you create a new data type.
- Once a struct is defined, you can create variables of the new type.

```
StudentRecord stu;
```

# Accessing Members

- You can treat the members of a struct just like variables.
- You need to use the *member access operator* `'.'` (pronounced "dot"):

```
cout << stu.name << endl;  
    stu.hw[2] = 82.3;  
    stu.ave = total/100;
```

# Structure Assignment

- You can use structures just like variables:

```
StudentRecord s1,s2;
```

```
s1.name = "Joe Student";
```

```
...
```

```
s2 = s1;
```

**Copies the entire structure**

# Be Careful

If a member is a pointer, *copying* means ■  
copying the pointer (not what is pointed  
.to)

# Probably not what you want

```
StudentRecord s1,s2;  
s1.name = "Joe Student";  
...  
s2 = s1;  
s2.name = "Jane Doe";  
  
// now s1.name and s2.name are both  
// "Jane Doe"
```

# Pointers to Structures

- Pointers to structures are used often.
- There is another *member access operator* used with pointers: ->

! "it looks like a "pointer"

```
StudentRecord *sptr;
```

```
...
```

```
cout << "Name is" << sptr->name;
```

```
cout << "Ave is " << sptr->ave;
```

# Sample Function (won't work!)

```
void update_average( StudentRecord stu) {  
    double tot=0;  
  
    for (int i=0;i<3;i++)  
        tot += stu.hw[i];  
    for (int i=0;i<3;i++)  
        tot += stu.test[i];  
    stu.ave = tot/5;  
}
```

# This one works

```
void update_average( StudentRecord *stu)
{
;double tot=0

for (int i=0;i<3;i++)
;tot += stu->hw[i]
for (int i=0;i<3;i++)
;tot += stu->test[i]
;stu->ave = tot/5
{
```

# Or use a reference parameter

```
void update_average( StudentRecord &stu) {  
    double tot=0;  
  
    for (int i=0;i<3;i++)  
        tot += stu.hw[i];  
    for (int i=0;i<3;i++)  
        tot += stu.test[i];  
    stu.ave = tot/5;  
}
```

# Other stuff you can do with a struct

- You can also associate special functions with a structure (called *member functions*).
- A C++ *class* is very similar to a structure, we will focus on classes.
  - Classes can have (data) members
  - Classes can have member functions.
  - Classes can also *hide* some of the members (functions and data).

# Quick Example

```
struct StudentRecord {  
    char *name;           // student name  
    double hw[3];         // homework  
    grades  
    double test[2];       // test grades  
    double ave;           // final average  
  
    void print_ave() {  
        cout << "Name: " << name << endl;  
        cout << "Average: " << ave << endl;  
    }  
};
```

# Using the member function

```
;doubleStudentRecord stu
```

```
set values in the structure // ...
```

```
;()stu.print_ave
```

# C++ Classes & Object Oriented Programming : Exerted from

*[elearning.najah.edu/OldData/pdfs/C++%20Classes%20Tutorials.ppt](http://elearning.najah.edu/OldData/pdfs/C++%20Classes%20Tutorials.ppt)*

# Object Oriented Programming

- Programmer *thinks* about and defines the attributes and behavior of objects.
- Often the objects are modeled after real-world entities.
- Very different approach than *function-based* programming (like C).

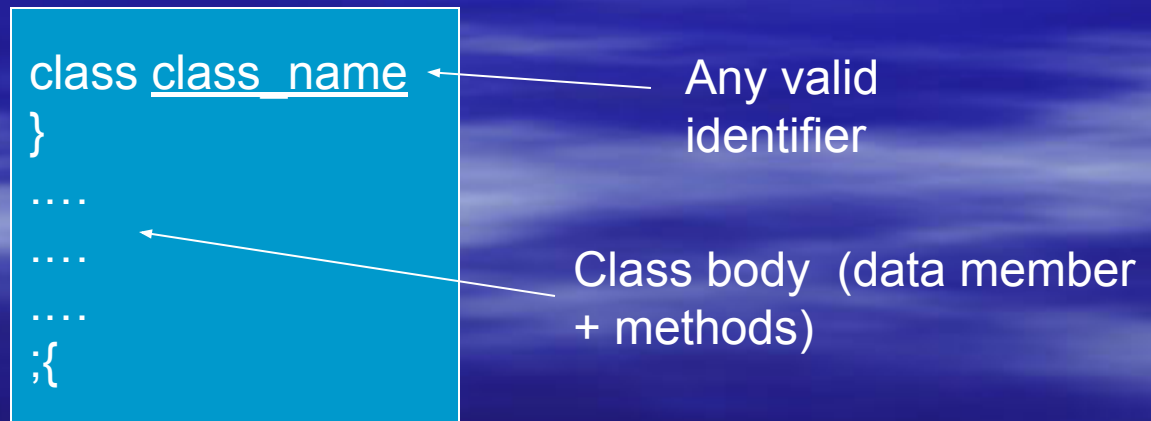

# Object Oriented Programming

- Object-oriented programming (OOP)
  - Encapsulates data (attributes) and functions (behavior) into packages called classes.
- So, Classes are user-defined (programmer-defined) types.
  - Data (data members)
  - Functions (member functions or methods)
- In other words, they are structures + functions

# Classes in C++

- A class definition begins with the keyword *class*.
- The body of the class is contained within a set of braces, **{ }**; (notice the semi-colon).

# ++Classes in C

- Within the body, the keywords *private:* and *public:* specify the access level of the members of the class.
  - the default is *private*.
- Usually, the data members of a class are declared in the *private:* section of the class and the member functions are in *public:* section.

# Classes in C++

```
class class_name
{
:private
    ...
    ...
    ...
    public:
    ...
    ...
    ...
;{
```

private members or  
methods

Public members or methods

# Classes in C++

- Member access specifiers
  - **public:**
    - can be accessed outside the class directly.
      - The public stuff is *the interface*.
  - **private:**
    - Accessible only to member functions of class
    - Private members and methods are for internal use only.

# Class Example

- This class example shows how we can encapsulate (gather) a circle information into one package (unit or class)

```
class Circle
{
    private:
        double radius;
    public:
        void setRadius(double r); double
        getDiameter();
        double getArea();
        double getCircumference();
};
```

No need for others classes to access and retrieve its value directly. The class methods are responsible for that only.

They are accessible from outside the class, and they can access the member (radius)

# Creating an object of a Class

- Declaring a variable of a class type creates an **object**. You can have many variables of the same type (class).
  - *Instantiation*
- Once an object of a certain class is instantiated, a new memory location is created for it to store its data members and code
- You can instantiate many objects from a class type.
  - Ex) `Circle c; Circle *c;`

# Special Member Functions

## ■ **Constructor:**

- Public function member
- called when a new object is created (instantiated).
- Initialize data members.
- Same name as class
- No return type
- Several constructors
  - Function overloading

# Special Member Functions

```
class Circle
{
    private:
        double radius;
    public:
        Circle();
        Circle(int r);
        void setRadius(double r);
        double getDiameter();
        double getArea();
        double getCircumference();
};
```

Constructor with no  
argument

Constructor with one  
argument

# Implementing class methods

- Class implementation: writing the code of class methods.
- There are two ways:
  1. Member functions defined outside class
    - Using Binary scope resolution operator ( :: )
    - “Ties” member name to class name
    - Uniquely identify functions of particular class
    - Different classes can have member functions with same name
- Format for defining member functions

```
ReturnType ClassName::MemberFunctionName ( ) {  
    ...  
}
```

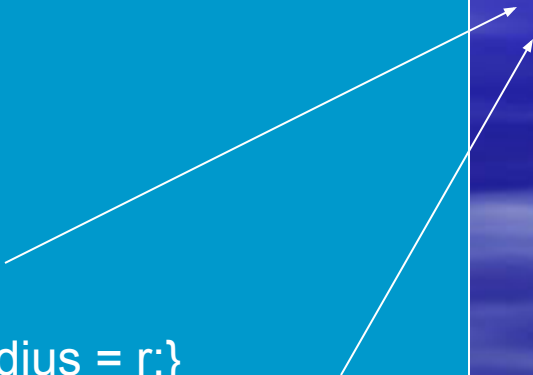

# Implementing class methods

## 2. Member functions defined inside class

- Do not need scope resolution operator, class name;

```
class Circle
{
    private:
        double radius;
    public:
        Circle() { radius = 0.0;}
        Circle(int r);
        void setRadius(double r){radius = r;}
        double getDiameter(){ return radius *2;}
        double getArea();
        double getCircumference();
};
```

Defined  
inside  
class

```
class Circle
{
    private:
        double radius;
    public:
        Circle() { radius = 0.0;}
        Circle(int r);
        void setRadius(double r){radius = r;}
        double getDiameter(){ return radius *2;}
        double getArea();
        double getCircumference();
};

Circle::Circle(int r)
{
    radius = r;
}

double Circle::getArea()
{
    return radius * radius * (22.0/7);
}

double Circle:: getCircumference()
{
    return 2 * radius * (22.0/7);
}
```

Defined outside class

# Accessing Class Members

- Operators to access class members
  - Identical to those for **structs**
  - Dot member selection operator (.)
    - Object
    - Reference to object
  - Arrow member selection operator (->)
    - Pointers

```
class Circle
```

```
{
```

```
private:
```

```
double radius;
```

```
public:
```

```
Circle() { radius = 0.0;}
```

```
Circle(int r);
```

```
void setRadius(double r){radius = r;}
```

```
double getDiameter(){ return radius *2;}
```

```
double getArea();
```

```
double getCircumference();
```

```
};
```

```
Circle::Circle(int r)
```

```
{
```

```
radius = r;
```

```
}
```

```
double Circle::getArea()
```

```
{
```

```
return radius * radius * (22.0/7);
```

```
}
```

```
double Circle::getCircumference()
```

```
{
```

```
return 2 * radius * (22.0/7);
```

```
}
```

The first

The second  
constructor is  
called

Since radius is a  
private class data  
member

```
void main()
```

```
{
```

```
Circle c1,c2(7);
```

```
cout<<"The area of c1:"  
<<c1.getArea()<<"\n";
```

```
//c1.radius = 5;//syntax error  
c1.setRadius(5);
```

```
cout<<"The circumference of c1:"  
<< c1.getCircumference()<<"\n";
```

```
cout<<"The Diameter of c2:"  
<<c2.getDiameter()<<"\n";
```

```
}
```

```
class Circle
{
    private:
        double radius;
    public:
        Circle() { radius = 0.0;}
        Circle(int r);
        void setRadius(double r){radius = r;}
        double getDiameter(){ return radius *2;}
        double getArea();
        double getCircumference();
};

Circle::Circle(int r)
{
    radius = r;
}

double Circle::getArea()
{
    return radius * radius * (22.0/7);
}

double Circle:: getCircumference()
{
    return 2 * radius * (22.0/7);
}
```

```
void main()
{
    Circle c(7);
    Circle *cp1 = &c;
    Circle *cp2 = new Circle(7);

    cout<<"The are of cp2:"
         <<cp2->getArea();
}
```

# Destructors

- Destructors
  - Special member function
  - Same name as class
    - Preceded with tilde (~)
  - No arguments
  - No return value
  - Cannot be overloaded
  - Before system reclaims object's memory
    - Reuse memory for new objects
    - Mainly used to de-allocate dynamic memory locations

# Another class Example

- This class shows how to handle time parts.

```
class Time
{
    private:
        int *hour,*minute,*second;
    public:
        Time();
        Time(int h,int m,int s);
        void printTime();
        void setTime(int h,int m,int s);
        int getHour(){return *hour;}
        int getMinute(){return *minute;}
        int getSecond(){return *second;}
        void setHour(int h){*hour = h;}
        void setMinute(int m){*minute = m;}
        void setSecond(int s){*second = s;}
        ~Time();
};
```

Destructor

Dynamic locations  
should be allocated  
to pointers first

```
Time::Time()
{
    hour = new int;
    minute = new int;
    second = new int;
    *hour = *minute = *second = 0;
}

Time::Time(int h,int m,int s)
{
    hour = new int;
    minute = new int;
    second = new int;
    *hour = h;
    *minute = m;
    *second = s;
}

void Time::setTime(int h,int m,int s)
{
    *hour = h;
    *minute = m;
    *second = s;
}
```

```
void Time::printTime()  
{  
    cout<<"The time is : ("<<*hour<<":"<<*minute<<":"<<*second<<") "  
        <<endl;  
}
```

Destructor: used here to  
de-allocate memory locations

```
Time::~~Time()  
{  
    delete hour; delete minute; delete second;  
}
```

```
void main()  
{  
    Time *t;  
    t= new Time(3,55,54);  
    t->printTime();  
  
    t->setHour(7);  
    t->setMinute(17);  
    t->setSecond(43);  
  
    t->printTime();  
  
    delete t;  
}
```

Output:

The time is : (3:55:54)  
The time is : (7:17:43)  
Press any key to continue

When executed, the  
destructor is called

# Reasons for OOP

1. Simplify programming
2. Interfaces
  - Information hiding:
    - Implementation details hidden within classes themselves
3. Software reuse
  - Class objects included as members of other classes

```
■ for(i=0;i<3;i++)  
■ {  
■     for(j=0;j<3;j++)  
■     {  
■         for(m=0;m<3;m++)  
■         {  
■             X[i][j][m]=A[i][m]*B[m][j];  
■             C[i][j]+=X[i][j][m];  
■         }  
■     }  
■ }
```

# Class Activity

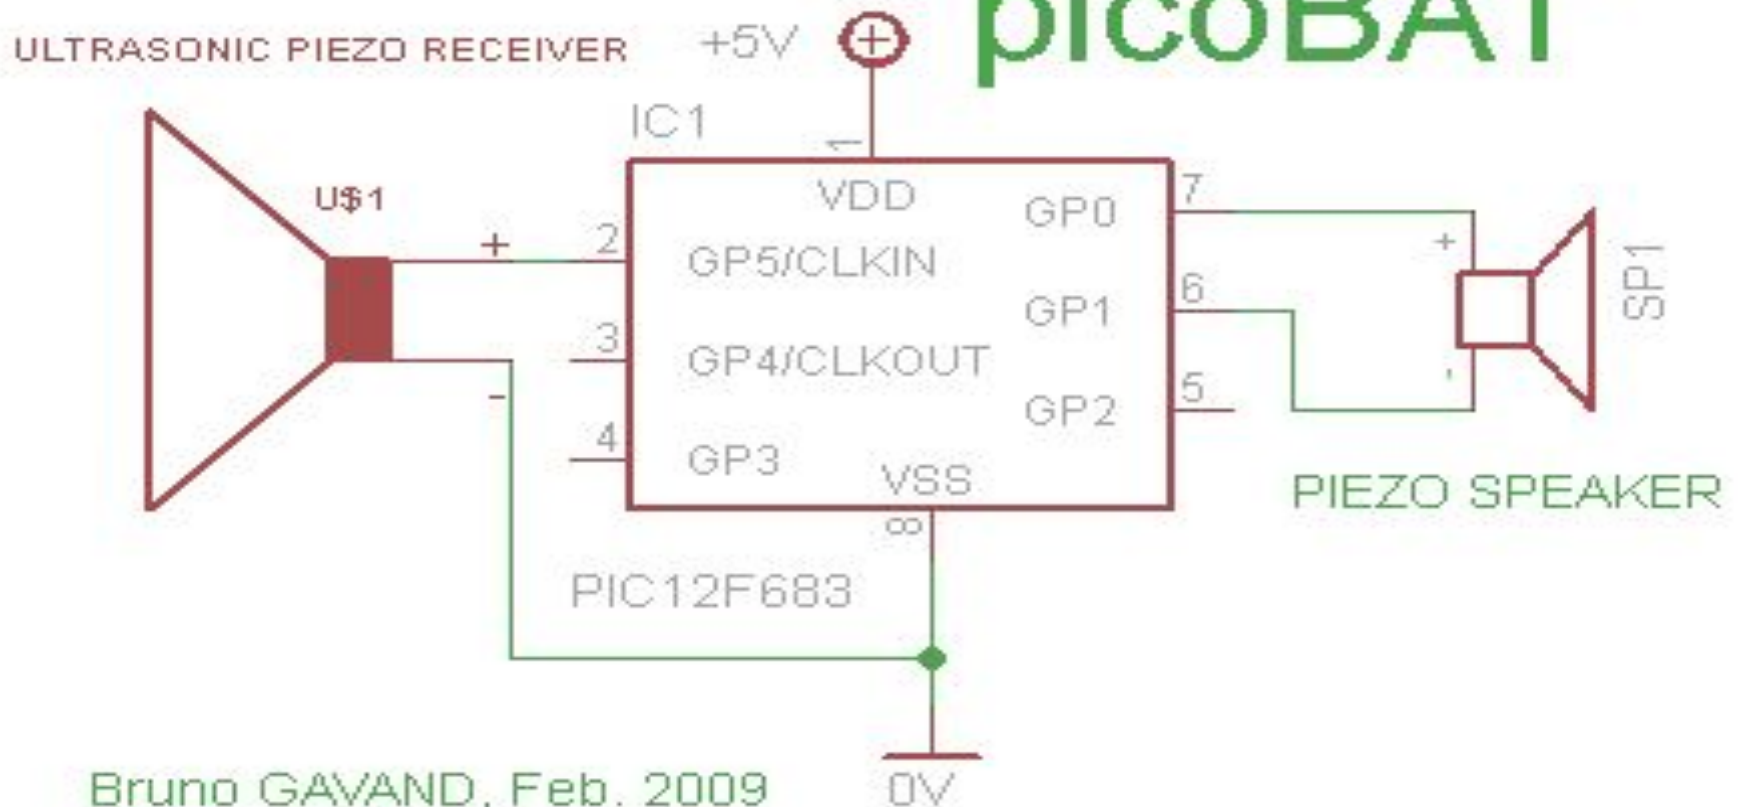

- Write a program to compute an area of a rectangle and triangle using the class concept?

Compilers PIC Compilers

**mikroC PRO for PIC**  
C compiler for PIC<sup>®</sup>12, PIC<sup>®</sup>16 and PIC<sup>®</sup>18

- FREE UPDATES OF A NEW COMPILER VERSIONS
- FREE PRODUCT LIFETIME TECHNICAL SUPPORT
- OVER 434 PIC MICROCONTROLLERS SUPPORTED
- WIDE-RANGE OF HARDWARE AND SOFTWARE LIBRARIES

**mikroC PRO for PIC**

mikroC PRO for PIC is a full-featured C compiler for PIC microcontrollers from Microchip. It is designed for developing, building and debugging PIC-based embedded applications. This development environment has a wide range of features such as easy-to-use IDE, very compact and efficient code, hardware and software libraries, comprehensive documentation, software simulator, hardware debugger support, COFF file generation and many more. Numerous ready-to-use examples will give you a good start for your embedded projects.

- ✓ Free lifetime product technical support.
- ✓ Free updates of new compiler versions.
- ✓ Over 434 PIC microcontrollers supported.
- ✓ Many hardware and software libraries.
- ✓ Numerous ready-to-use practical examples.
- ✓ User-friendly IDE with additional tools.
- ✓ Easy-to-understand documentation.
- ✓ ANSI C compiler with minor modifications.
